ABSTRACT

Seed is a major and important input in potato (*Solanum tuberosum* L.) cultivation. (propagation, the requirement of seed potatoes (tubers) is voluminous and accounts for 40 production. Potato productivity in India is low in comparison to developed countries due quality seed in required amounts. Seed potato production through micro-propagation (tissu overcome the problems associated with the conventional multiplication system. The eve potatoes in most of the potato growing countries can be solved through hi-tech seed pro micro-propagation and aeroponic techniques. Besides, rapid multiplication, production of d under controlled conditions followed by reduced number of field exposures as compared to c system, is an added advantage of seed potato production in these techniques. For expanding qu production systems framework needs to be reviewed. The present review will be an endeavo background of seed potato production, issues and challenges, supply frameworks and poli

Key words: Health status, Hi-tech system, Meristem culture, Seed, Seed plot

Seed is the basic and vital input in agriculture and its timely availability in adequate quantity as per demand decides the strength and growth of agricultural economy in a country. Seed has played a very important role in India's green revolution and shall continue to be the important component in the days to come (Naik and Buckseth 2018). The traditional farmers' practices are to save their own seeds generally selected from healthy plants from fields which are free from diseases and pests, harvest them separately, clean, cure and then store in containers and inspect regularly for any kind of damage; or they get quality seed from other seed producing farmers on barter basis, indicating thereby the importance of seed in their production system.
